## A Detailed derivation of the weighted ELBO

We simplify the notation and write the distribution of the inference model over a subsequence  $\mathbf{h}_{i...j}$ as  $q(\mathbf{h}_{i...j}) = \prod_{t=i}^{j} q(\mathbf{h}_t | \mathbf{h}_{t-1}, w_{t...T})$  for any  $1 \leq i \leq j \leq T$  without making the dependency on  $\mathbf{h}_{i-1}$  and the data explicit. Furthermore, let  $\mathcal{K}_t = {\{\mathbf{h}_t^{(k)}\}}_{k=1}^K \sim q(\mathbf{h}_t)$  be short for a set of  $K$ samples of  $\mathbf{h}_t$  from the inference model. Finally, let  $\theta$  summarize all parameters of both, generative and inference model.

The key idea is to write the marginal as a nested expectation

$$
P(\mathbf{w}) = \mathbb{E}_{q(\mathbf{h}_1)} \Big[ P(w_1, \mathbf{h}_1) \mathbb{E}_{q(\mathbf{h}_{2...T})} \left[ P(w_{2...T}, \mathbf{h}_{2...T} | \mathbf{h}_1) \right] \Big] \tag{14}
$$

and observe that we can perform an MC estimate with respect to  $\mathbf{h}_1$  only

<span id="page-0-3"></span>
$$
P(\mathbf{w}) \approx \mathbb{E}_{\mathcal{K}_1} \left[ P(w_1, \mathbf{h}_1) \mathbb{E}_{q(\mathbf{h}_2...T)} \left[ P(w_{2...T}, \mathbf{h}_{2...T} | \mathbf{h}_1^{(k)}) \right] \right]
$$
(15)

The same argument applies for  $\frac{P(w,h)}{q(h)}$ , the integrand in the ELBO. Now we can repeat the IWAE argument from [\[BGS15\]](#page--1-0) for the outer expectation

$$
\log P(\mathbf{w}) = \log \mathbb{E}_{q(\mathbf{h})} \left[ \frac{P(\mathbf{w}, \mathbf{h})}{q(\mathbf{h})} \right]
$$
(16)

$$
= \log \mathbb{E}_{q(\mathbf{h}_1)} \left[ \frac{P(w_1, \mathbf{h}_1)}{q(\mathbf{h}_1)} \mathbb{E}_{q(\mathbf{h}_2...T)} \left[ \frac{P(w_{2...T}, \mathbf{h}_{2...T} | \mathbf{h}_1)}{q(\mathbf{h}_{2...T})} \right] \right]
$$
(17)

$$
= \log \mathbb{E}_{\mathcal{K}_1} \left[ \frac{1}{K} \sum_{k=1}^K \frac{P(w_1, \mathbf{h}_1^{(k)})}{q(\mathbf{h}_1^{(k)})} \mathbb{E}_{q(\mathbf{h}_{2...T})} \left[ \frac{P(w_{2...T}, \mathbf{h}_{2...T} | \mathbf{h}_1^{(k)})}{q(\mathbf{h}_{2...T})} \right] \right]
$$
(18)

$$
\geq \mathbb{E}_{\mathcal{K}_1} \left[ \log \frac{1}{K} \sum_{k=1}^K \frac{P(w_1, \mathbf{h}_1^{(k)})}{q(\mathbf{h}_1^{(k)})} \mathbb{E}_{q(\mathbf{h}_{2...T})} \left[ \frac{P(w_{2...T}, \mathbf{h}_{2...T} | \mathbf{h}_1^{(k)})}{q(\mathbf{h}_{2...T})} \right] \right] = \mathcal{L}
$$
(19)

where we have used the above factorization in [\(17\)](#page-0-0), MC sampling in [\(18\)](#page-0-1) and Jensen's inequality in [\(19\)](#page-0-2). Now we can identify

$$
\omega_1^{(k)} = \frac{P(w_1, \mathbf{h}_1^{(k)})}{q(\mathbf{h}_1^{(k)})} \mathbb{E}_{q(\mathbf{h}_{2...T})} \left[ \frac{P(w_{2...T}, \mathbf{h}_{2...T} | \mathbf{h}_1^{(k)})}{q(\mathbf{h}_{2...T})} \right]
$$
(21)

and use the log-derivative trick to derive gradients

<span id="page-0-4"></span><span id="page-0-2"></span><span id="page-0-1"></span><span id="page-0-0"></span>
$$
\nabla \mathcal{L} = \mathbb{E}_{\mathcal{K}} \left[ \sum_{k=1}^{K} \frac{\omega_1^{(k)}}{\sum_{k'} \omega_1^{(k')}} \nabla \log \omega_1^{(k)} \right]
$$
(22)

Again, we have omitted carrying out the re-parametrization trick explicitly when moving the gradient into the expectation and refer to the original paper for a more rigorous version. The gradient of the logarithm decomposes into two terms,

$$
g_t^1 = \nabla \log \frac{P(w_1, \mathbf{h}_1)}{q(\mathbf{h}_1)}
$$
(23)

$$
g_t^2 = \nabla \log \mathbb{E}_{q(\mathbf{h}_{2...T})} \left[ \frac{P(w_{2...T}, \mathbf{h}_{2...T} | \mathbf{h}_1)}{q(\mathbf{h}_{2...T})} \right]
$$
(24)

The first is the contribution to our original ELBO normalized by the IWAE MC weights. The second is identical to our starting-point in [\(16\)](#page-0-3) but for  $t = 2...T$  and conditioned on  $\mathbf{h}_1^{(k)}$ . Iterating the above for  $t = 2 \dots T$  yields the desired bound.

To allow tractable gradient computation using the importance-weighted bound, we use two simplifications. First, we limit the computation of the weights  $\omega_t^{(k)}$  to a finite horizon of size 1 which reduces them to only the first factor in [\(21\)](#page-0-4). Second, we forward only a single sample  $h_t$  to the next time-step to remain in the usual single-sample sequential ELBO regime (which is important as  $g_t^2$  depends on  $\mathbf{h}_{t-1}$ ). That is, we sample  $\mathbf{h}_t$  proportional to the weights  $\omega_t^{(k)} \dots \omega_t^{(k)}$ . A more sophisticated solution would be to incorporate techniques from particle filtering which maintain a fixed-size sample population  $\{\mathbf{h}_t^{(1)}, \ldots, \mathbf{h}_t^{(K)}\}$  that is updated over time.
