A Generalized Conditional Gradient Algorithm

In this section, we provide details on the latest generalized conditional gradient descent algorithm proposed in [\[9\]](#page-0-0). We first provide an alternative formulation of the objective function, and then present the general algorithm.

A.1 Alternative Formulation

Directly solving the objective [\(7\)](#page-0-1) is difficult since the nonnegative constraints are entangled with the non-smooth nuclear norm penalty. To address this challenge, we use a simple penalty method. Specifically, given $\rho > 0$, we arrive at the next formulation [\(8\)](#page-0-2) by introducing two auxiliary variables *Z*¹ and *Z*² with some penalty function, such as the squared Frobenius norm.

$$
\min_{\eta \geqslant 0, \boldsymbol{X} \geqslant 0, \boldsymbol{Z}_1, \boldsymbol{Z}_2} \ell(\eta, \boldsymbol{X}) + \gamma \|\boldsymbol{X} - \boldsymbol{X}^\top\|_F^2 + \alpha \|\boldsymbol{Z}_1\|_* + \beta \|\boldsymbol{Z}_2\|_* + \rho \|\boldsymbol{\eta} - \boldsymbol{Z}_1\|_F^2 + \rho \|\boldsymbol{X} - \boldsymbol{Z}_2\|_F^2
$$
\n(8)

The new formulation [\(8\)](#page-0-2) allows us to handle the non-negativity constraints and nuclear norm regularization terms separately.

A.2 Alternating Updates between Proximal Graident and Conditional Gradient

Now, we present Algorithm [1](#page-0-3) that can solve [\(8\)](#page-0-2) efficiently. For notation simplicity, we first set

$$
f(\eta, X, Z_1, Z_2) = \ell(\eta, X) + \gamma \|X - X^\top\|_F^2 + \rho \|\eta - Z_1\|_F^2 + \rho \|X - Z_2\|_F^2
$$

At each iteration, we apply cheap projection gradient for block $\{n, X\}$ and cheap linear minimization for block $\{Z_1, Z_2\}$. Specifically, the algorithm consists of two main alternating subroutines:

Proximal Gradient. When updating $\{n, X\}$, we directly compute the associated proximal operator, which in our case, reduces to the simple projection as follows,

$$
X^{k} = (X^{k-1} - \xi \nabla_{X} f(X^{k-1}, \eta^{k-1}, Z_{1}^{k-1}, Z_{2}^{k-1}))_{+}
$$

\n
$$
\eta^{k} = (\eta^{k-1} - \xi \nabla_{\eta} f(X^{k-1}, \eta^{k-1}, Z_{1}^{k-1}, Z_{2}^{k-1}))_{+}
$$

where $(\cdot)_+$ simply sets the negative coordinates to zero.

Conditional Gradient. When updating $\{Z_1, Z_2\}$, we use the conditional gradient algorithm that successively linearizes *f* and finds a descent direction by solving:

$$
Y_1^k = \underset{\|\mathbf{Y}\|_* \leq 1}{\operatorname{argmin}} \left\langle \mathbf{Y}, \nabla_{\mathbf{Z}_1} f(\mathbf{X}^k, \boldsymbol{\eta}^k, \mathbf{Z}_1^{k-1}, \mathbf{Z}_2^{k-1}) \right\rangle \tag{9}
$$

and then takes the convex combination $Z_1^k = (1 - \delta_k)Z_1^{k-1} + \delta_k \theta_k Y_1^k$ with a suitable step size η_k and scaling factor θ_k . The minimizer of [\(9\)](#page-0-4) is the outer product of the top singular vector pair of $-\nabla_{\mathbf{Z}_1} f(\mathbf{X}^k, \boldsymbol{\eta}^k, \mathbf{Z}_1^{k-1}, \mathbf{Z}_2^{k-1})$, which can be computed efficiently in linear time using Lanczos algorithm [\[8\]](#page-0-5). Next we perform a line search to find $\theta_k = \operatorname{argmin}_{\theta \geq 0} h^1(\theta_k)$, where $h^1(\theta_k) = f(Z_1^k) + \alpha \delta_k \theta_k$. Here $h^1(\theta_k)$ is the upper bound of the objective function at Z_1^k , and one can compute θ_k efficiently in close form. Similarly, one can repeat the same procedure for computing Z_2^k , and we use $h^2(\theta_k)$ to denote the linear search function for Z_2^k .
